Prospective study on vacuum assisted closure therapy in treatment of soft tissue injuries associated with Gustilo Anderson compound grade IIIB fractures

Venu Madhav HV and Balu C Babu

Abstract

Introduction: The aim of this prospective study is to know the rate of wound infection, number of days required for making the wound fit for skin cover procedures, number of days required for formation of uniform granulation tissue bed in the wound, number of days of hospital stay and healing of soft tissue injury in Gustilo Anderson compound grade IIIB fractures treated by Vacuum Assisted Closure & by stabilization of fracture.

Methodology: In our institution seventeen patients with Gustilo Anderson compound grade IIIB patients were selected for this prospective study. The study period is from November 2012 to September 2014. All patients were selected based on our inclusion and exclusion criteria. Only Gustilo Anderson compound grade IIIB fractures were included in the study.

Results: After VAC therapy, SSG was done to cover the healthy granulation tissue in 13 patients and flap cover was done for 4 patients.

Conclusion: The time duration taken for formation of healthy granulation tissue was less.

Keywords: Compound Fracture, VAC therapy, Gustilo Anderson
also the duration of hospital stay was reduced, number of debridement required were also few. The indirect effects of VAC therapy are reduced morbidity, earlier return to work, & cost effectiveness.

**Methodology**

In our institution seventeen patients with Gustilo Anderson compound grade IIIB patients were selected for this prospective study. The study period is from November 2012 to September 2014. All patients were selected based on our inclusion and exclusion criteria. Only Gustilo Anderson compound grade IIIB fractures were included in the study.

**Inclusion criteria**

1. Gustilo Anderson Compound Grade III B Fractures
2. Fractures with superficial infection

**Exclusion criteria**

1. Fractures with sequestrum
2. Pathological fractures
3. Chronic osteomyelitis

**Mode of injury**

1. Road traffic accidents : 14
2. Train traffic accidents : 2
3. Accidental fall : 1

**Age and Sex Distribution**

17 patients were treated with VAC therapy of age between 21yrs to 60yrs.
Among the 17 patients 15 were male and 2 were female

Assessment of wound before applying VAC therapy

1. Pus C/S
2. Size of wound
3. Area of the bone exposed
4. Area of tendons exposed
5. Any implants exposed
6. ESR
7. CRP

Initially the wound is thoroughly debrided and all the infected and foreign materials like mud etc. are removed and through wound wash is given. Antibiotics are given as soon as the patient is received in the emergency ward. Initially broad spectrum antibiotics are given and later specific antibiotics are given according to sensitivity profile.

**Results**

Our study includes seventeen patients treated with VAC therapy. Mean age of the group is 40.5 years. The age group 30-50 dominates the series accounting for 44% among the cases. Gustilo Anderson compound grade III B fractures caused by road traffic accidents includes 14 cases (82.35%), train traffic accident 2 cases (11.76%) and accidental fall 1 case (5.88%).

The average duration of treatment was 10.5 days (9–12 days), and on an average the dressing change was 3.3 times. Infection rate. Among the non infected cases (14 cases) only one case showed infection and among the infected cases (3 cases) one case showed infection at the end of treatment for which additional wound debridement and appropriate antibiotics were given and later wound cover was done.

Duration of wound healing Mean wound size reduction at treatment completion 15mm (10-20mm), 15 patients among the 17 achieved good wound healing and the tendons which were exposed were adequately covered by granulation tissue. The mean duration required for formation of healthy uniform granulation bed was 10.5 days (9-12 days).

After VAC therapy, SSG was done to cover the healthy granulation tissue in 13 patients and flap cover was done for 4 patients.

In two patients infection was reduced and these wounds were thoroughly debrided and flap cover was done to cover exposed bone. Duration of hospital stay- as the patient load is very high in our institute the definitive management of the fractures was delayed and the average duration of hospital stay one and a half month (range 1month -2 months)

There were no complications in our study like bleeding overgrowth of granulation tissue over the foam or deep infections.

**Table 1:** Distribution of Cases Based On Age

<table>
<thead>
<tr>
<th>Sl. no</th>
<th>Age In Years</th>
<th>Number of patients</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21-30</td>
<td>6</td>
<td>35.29</td>
</tr>
<tr>
<td>2</td>
<td>31-50</td>
<td>8</td>
<td>47.05</td>
</tr>
<tr>
<td>3</td>
<td>51-60</td>
<td>3</td>
<td>17.64</td>
</tr>
<tr>
<td>Total</td>
<td>17</td>
<td>100</td>
<td></td>
</tr>
</tbody>
</table>

From the above table it is very clear that majority of cases occurred in 31-50 years age group correlating with common occurrence of RTA in that age.

**Table 2:** Distribution Based On Location of Injury

<table>
<thead>
<tr>
<th>Sl. no</th>
<th>Site</th>
<th>No. of cases</th>

<td>17</td>
<td>100%</td>
</tr>
</tbody>
</table>

Gustilo Anderson compound grade IIIB fractures are associated with bone exposure and tendons are also exposed in few cases depending on the site of the defect. Tendons are more commonly exposed in forearm.

**Table 4:** Distribution based on number of dressings applied

<table>
<thead>

Discussion

Management of soft tissue plays a very important role in Gustilo Anderson compound fractures. Many factors play a coordinated role in wound healing like the wound environment the composition of the wound which includes physical characters of the wound, chemical composition of the wound, biological structure of the wound etc. all these play an important role in the healing.

The goals of soft tissue management are
1. Controlling bleeding.
2. New granulation tissue should replace the soft tissue defects.
3. The soft tissue defect should be covered by SSG or flap cover as soon as possible.

Many factors affect the wound healing like8
1. Defect in vascular supply.
2. Defect in angiogenesis.
3. Defect in laying matrix proteins.
4. Defect in locally acting growth factors.
5. Defects in clearing the dead and necrotic cells.
7. Defect in enzymes which lyse the defective cells.
8. Defect in production of new proteins for the wound.

Any of these factors or a combination of these factors affect the wound healing and the wound goes into a stage of chronic non healing. After applying VAC therapy the negative force causes more blood circulation to the wound, reduces the burden of bacterial infection and supplies more oxygen to the affected soft tissue.

Rate of infection- In our study rate of infection was 11.76% and we compared our result with the following literature study where the soft tissue injuries were managed by saline dressings9 Henley et al, JOT 1998- 34.7%10, Charalambous et al, Injury 2005-27%11, Gopal et al, JBJS-B 2004-27.4%12 Duration required for forming new healthy granulation bed.

In our study an average of 10.5 days was taken for formation of a uniform healthy granulation bed of the wound. Similar studies were conducted by Argenta et al., Morykwas et al, 13, & Joseph et al, 14, & these studies also showed that VAC proved effective in shrinking of the diameter of the wound size and formation of healthy granulation tissue when compared to normal saline dressing methods.

Microscopically application of VAC therapy also showed increase in formation of new blood vessels and formation matrix tissue but the wounds treated by saline dressing showed inflammatory tissue & fibrous tissues as compared by above studies.

The uniform negative pressure delivered by the VAC therapy to the wound bed plays a significant role in formation of new healthy granulation tissue.

In normal saline dressings the gauze pad sticks to the dead tissue and while changing the dressings the dead tissue along with the new and delicate tissue formed underneath is also removed along with the gauze pad and this causes mechanical damage to the formation of new granulation tissue in the wound bed.

Duration of hospital stay- As the patient load was very high and availability of OT is limited in our institution the definitive management like split skin grafting, flap cover and fixation of the fractures was delayed and hence the duration of hospital stay was prolonged in our study.

Studies on application of VAC therapy on compound fractures is very less. And these compound fractures have high chances of going in for non union and secondary infection if they are not adequately treated. These wounds should be thoroughly debrided and skin cover should be given as soon as possible as the exposed bones, tendons & neuovascular structures should be covered as soon as possible to save these structures from infection.

The high cost of vacuum system and the cost of vacuum dressing has discouraged many doctors from its application but when compared with saline dressings which take longer duration for wound healing, more number of debridement & more number of days of absence from work when all these factors are compared with expense of VAC the treatment expense of VAC is lesser with also lesser morbidity to the patient. And lesser hospital stay and the hospital beds can be used for other patients.

VAC therapy has wide range of benefits it can be applied to most of the wounds but all wounds cannot be treated by VAC therapy. VAC causes bone exposed wound to be covered by granulation tissue which requires a simple split skin graft to cover the granulation tissue whereas the bone exposed area needs a more time consuming and more expertized flap cover for covering the wound.

Conclusion

- The rate of wound infection was significantly reduced.
- The wound was fit for definitive skin cover procedures like SSG & flap cover at a faster rate.
- The number of debridement of the wound were reduced.
- The granulation tissue formed was healthy and uniform.
- Soft tissue defects which lead to ugly and irregular surface was avoided by forming uniform granulation tissue and the defects were covered.
