Study of patellar fractures treated by modified tension band wiring—A prospective study

Muralidhar BM, Madhusudan H and Mithun Mohan

DOI: http://dx.doi.org/10.22271/ortho.2017.v3.i2j.93

Abstract
Background and objectives: Patellar fractures are common and it constitutes about 1% of all skeletal injuries resulting from either direct or indirect trauma. Patella is of importance for the extension of knee joint, which increases the force of quadriceps apparatus by improving the leverage.
This study directed towards the functional results and complications of modified tension band wiring for patella fractures.

Materials and methods: This prospective study is done in Department of Orthopaedics at Sri Siddhartha medical college, hospital and Research Center Tumkur during the period from September 2015 and February 2017. This study consists of 20 cases of displaced transverse fracture patella treated by modified tension band wiring.

Results: In this study, average age was of 39.7 with male patients outnumbered the females by more than double, Right sided patellar fractures were predominant, 70% of our patients had no pain or only mild pain. Only 20% of our patients had significant extensor lag and nearly 80% had normal quadriceps strength. We had 70% excellent and 20% good and 10% poor results according to modified scale of bostman et al.

Conclusion: Our study shows that modified tension band wiring is a definitive procedure in management of displaced transverse patellar fracture with least complications. This surgery of modified tension band wiring helps for early mobilization post-operatively which plays an important role in final outcome. Early and continuous physiotherapy following surgery is a paramount importance in determining the end results.

Keywords: Modified tension band wiring, fracture patella, knee joint

Introduction
The patella is the largest sesamoid bone in the human body situated in front of knee in the tendon quadriceps femoris muscles. It is flattened, triangular distally and curved proximally with the thickness between 1.5cm and 2cm [1].
The patella is of importance for the extension of knee joint. It increases the force of the quadriceps apparatus by improving the leverage. In addition, it protects the anterior articular surface of distal femur against external violence.
Fractures of the patella constitute almost 1% of all skeletal injuries, resulting from either direct or indirect trauma [2].
Most are transverse fractures involving the middle third of the patella in patients aged 20 and 50yrs, and affect almost twice as many men as women.
Thomson in 1935 treated patellar fractures by surgical excision of small fragments and capsule repair. He suggested avoiding total patellectomy, because of the impairment of leverage of quadriceps during extension of knee [3].
Brookes and heygrooves in 1937 suggested that the patella inhibits the action of quadriceps tendon and they thought that the strength of the knee was improved with patellectomy [4, 5].
Haxton in 1945 on the basis of his experiments proved that patella improves the efficiency of the knee joint and demonstrated that the power of extension increases as the knee joint extends [6].
Cohn in 1944, found degenerative changes in patellectomised rabbits and concluded that procedure should avoided inhuman patients [7].
Scott in 1949 did clinical study of total patellectomy and reported increased incidence of pain and discomfort during movement of the knee [8]. O donoghue suggested that total patellectomy diminished the extensor power of the knee and resulted in various post patellectomy symptoms [9]. Muller in 1970 introduced anterior application of two stainless steel wires inserted through longitudinally drilled holes [10]. Marten. H.G. Heusinkveld et al study shows pain and irritation were most commonly present following this modality of treatment. Skin irritation, wire migration or K-wire loosening were observed. Modified tension band technique is currently the most widely accepted and several studies have shown a high percentage of good results. Several methods of internal fixation of fractured patella have been advocated. This dissertation is directed towards the clinical evaluation of patella fractures treated with modified tension band wiring.

Methods
The study was conducted in Sri Siddhartha Medical College, Tumkur from September 2015 and February 2017. This study consists of 20 cases of displaced transverse fracture patella treated by modified tension band wiring. The cases were selected based on inclusion and exclusion criteria

Aims and objectives
Aim of the study
To evaluate the clinical and functional outcome of modified tension band wiring for fractures of patella.

Objectives
To assess the functional results of modified tension band wiring in patellar fractures.
• To assess the complications of modified tension band wiring in patellar fractures.

Inclusion criteria
1. All closed and type Iopen displaced transverse patellar fractures.
2. Age >16 years < 60 yrs.
3. Sex: both male and female
4. Patient who are medically fit for the surgery

Exclusion criteria
1. Type II and type III compound fractures
2. Grossly comminuted, vertical or marginal fractures.
3. Old fractures (more than 2-3 weeks).
4. Undisplaced transverse fractures.

Methods used in the study
A prospective study comprising of patients identified for surgical treatment of transverse fracture of patella admitted to Sri Siddhartha Medical College

All patients in the study after undergoing routine clinical examination would be subjected to following battery of investigations complete haemogram with ESR Chest X ray PA view Electrocardiogram 2D echocardiogram

Once the patient is admitted to the hospital, the details of the cases were recorded including name, age, sex, occupation, address detailed clinical history, past history, family and personal history clinical history will be taken. Thorough general and clinical examination will be carried out. Routine blood investigation and Radiological investigations will be done. The limb will be immobilized by an above knee plaster of Paris posterior slab.

Patients will be explained in detail about surgery, possible complications and limitations to be followed after surgery.

Operative procedure
The fracture site will be exposed through transverse incision/ midline longitudinal incision in front of the knee; the fragments will be reduced and held in position with the help of patellar clamp or towel clips. Two Kirschner wires of 2 mm thickness are passed parallel to each other from above down wards starting at its superior border till lower pole of patella is reached. 18 G stainless steel wire is taken and passed deep to ligamentum patellae inferiorly and behind the quadriceps tendon superiorly making a figure of “8” in front of the patella sufficient tension is given. Tear in the quadriceps expansion is sutured with vicryl and wound closed in layers. Above Knee slab or pressure bandage is given as a temporary immobilization. Check X-Rays are done post operatively. The operated knee will immobilized in extension in an above knee posterior slab, and will be advised to do straight leg raising and weight bearing from third post-operative day. Sutures will be removed from 12th to 14th day and knee flexion exercise will be started with quadriceps board and with continuous passive motion machine.

Patients will be discharged from the hospital once they are fully mobilized and will be advised to do dynamic quadriceps exercise.

Follow up
The discharged patients were advised to report for follow up on every month, for 6 months, during each follow up the patients were examined for objective assessment including range of knee movement, extension lag, effusion, circumference of thigh, efficacy of quadriceps and questioned for subjective symptoms like pain, use of walking aid, giving away, stair case climbing, squatting which was recorded according to Modified Bostman scale [12].

Results
Age
In this study age of patients was ranging from 19 yrs to 65 yrs with median age of 39.5 yrs (SD ±12.607)

Gender
In this study 70% were males and 30% were females.

Side
In this study the fracture over the right side was 14 (70%) and left was 6 (30%).

No bilateral fracture cases reported

Mode and mechanism of injury
In this study 12 cases were fall on knee and 7 were road traffic accident, 1 was direct trauma at work.

In this study 60% of fractures were due to indirect mechanism as in forceful flexion of the knee against the contracted quadriceps, and 35% were due to RTA and 5% direct trauma to patella at work.

Functional outcome
In this study 10% had flexion <90, 10% were 90 - 120, 80% more than 120
In this study at the end of 6 months 70% had none or minimal pain, 20% had moderate on extension and 10% had during daily activities.

The complications seen in our study 1 case (5%) had superficial infection, 1 case (5%) had proximal migration of the k wires.

**Score**

In our study according to modified bostman score 14 (70%) cases were excellent, 4(20%) were good, 2(10%) were poor.

**Discussion**

**Age**

In this study age of patients was ranging from 19 yrs to 65 yrs with median age of 39.5 yrs (SD ±12.607) Sudheendra P.R, Krishna Prasad.S 13 study shows youngest patient was of 21 years age and oldest was 62 years of age. Smith et al. [14] mentioned the mean age as 48 years in their study.

**Gender**

In this study 70% were males and 30% were females. Anand. B. Jab Shetty [15] out of 20 cases, there were 15 males (75%) and 5 were females (25%)

**Side**

In this study the fracture over the right side was 14 (70%) and left was 6 (30%).

No bilateral fracture cases reported

Sudheendra P.R, Krishna Prasad.S [13] study shows that patellar fractures occurred on right side in 60.5% cases while 39.5% occurred on left side.

**Mode and mechanism of injury**

In this study 12 cases were fall on knee and 7 were road traffic accident, 1 was direct trauma at work.

In this study 60% of fractures were due to indirect mechanism as in forceful flexion of the knee against the contracted quadriceps, and 35% were due to RTA and 5% direct trauma to patella at work.

A.B.Jab Shetty [15] stated that commonest mode of injury was fall on knee, which was seen in 12 cases i.e., 60% of cases and the rest 40% had road traffic accident.

In A.B.Jabshetty [15] study, patients with fractures of ipsilateral limb were excluded from the study.

**Functional outcome**

In this study 10% had flexion <90, 10% were 90 - 120, 80% more than 120

Sudheendra P.R, Krishna Prasad.S [13] mentioned only one patient having range of knee motion of less than 90 degrees and was associated with a poor outcome.

In our study extensor lag more than 5 recorded (using goniometer) in 20%

Sudheendra P.R, Krishna Prasad.S [13] recorded Extensor lag of 5 or more degrees in 10 (23%) cases.

20% of cases in the study by Shrinivas et al [16].

Higher incidence of extensor lag in our series could be attributed due to associated fractures in two cases, and due to age (65years), weak quadriceps strength in 1 case and poor motivation and superficial infection in other case.

Quadriceps power was of grade v in 80% and grade 4 in remaining cases.

This compares favorably with the Alglietti and Buzzi [17] series who observed normal strengths in 72%.

In this study at the end of 6 months 70% had none or minimal pain, 20% had moderate on extension and 10% had during daily activities.

Sudheendra P.R, Krishna Prasad.S [13] accounted 74% with none or minimal, and 10% with moderate, and 2 had preexisting patellofemoral OA.

In contrast to this Aglietti and Buzzi has 79% with none or mild pain and 21% with moderate pain. This might be due to long duration of follow up (upto 18 months).

The complications seen in our study 1 case (5%) had superficial infection, but in the study of Srinivas et al [16], no infection was noted.

In this study 1 case (5%) had proximal migration of the k wires.

John J et al [17] study mentioned loosening of K-wires is considered the main complication of the modified K-wire band fixation of patella fracture.

Wang Chengxue et al [18] recorded 5 out of (6.9%) patients with the modified K-wire tension band were badly affected by skin irritation probably due to K-wire prominence and migration.

Marten.H.G. Heusinkveld [19] et al (2013) study shows pain and irritation were most commonly present following this modality of treatment. Skin irritation, wire migration or K-wire loosening were observed.

**Score**

In our study according to modified bostman score 14 (70%) cases were excellent, 4(20%) were good, 2(10%) were poor.

Attique Ur Rehman Qureshi [20] recorded excellent results in 36.67% and 56.67% with good results,

Sudheendra P.R, Krishna Prasad.S [13] recorded Excellent in 58% (25 cases), Good in 16% (7 cases) Fair in 18.6 (8 cases) and Poor in 4.7% (2 cases)

Anand. B. Jab Shetty [15] mentioned the cases treated with modified tension band wire, excellent to good results were seen in 90% of cases.

According to Shrinivas et al [16] 80% of cases treated with modified tension band wiring shown to have excellent to good results and 20% shown poor results.

However only transverse fracture of patella was included in this study.

The study was limited due to less period of time, and a longer duration of follow-up may be necessary to determine the true incidence and impact of patello-femoral arthritis.

Schimitsch [21] et al observed that open reduction and internal fixation of patella fractures restores excellent limb and health status.

**Summary**

- In this study 26-35 and 46-55 age groups incidence were more with the mean of 39.7.
- In our study, male patients outnumbered the females by more than double.
- Right sided patellar fractures were predominant.
- All fractures selected were of transverse type.
- 10% of our patients had associated injury with extensor lag.
- Modification with longitudinal K-wires was the preferred tension band wiring technique.
- Longitudinal midline skin incisi8on was used in all cases.
- 70% of our patients had no pain or only mild pain.
- Only 4(20%) of our patients had significant extensor lag.
- Nearly 80%our patients had normal quadriceps strength.
In our study, 90% > 90 of knee flexion.
The fixation technique did not affect the function of walking.
70% cases were excellent and 20% were good.

**Conclusion**
The study was conducted on 20 fresh patellar fractures during September 2015 and February 2017 with age group varying from 16 to 60yrstreated by modified tension band wiring technique.
In patella fractures the most significant effects are loss of continuity of extensor mechanism of the knee.
The study shows that treatment of patella fractures with modified tension band wiring is a definitive treatment with minimal complications and good functional outcome.
The surgery helps for early mobilization post operatively.
Modified tension band wiring technique, eventually results in a favorable outcome in terms of satisfactory return of knee function.
Early and continuous physiotherapy following the surgery is a paramount importance in determining the end results.
This study favours that modified tension band wiring is the better choice for treatment of patella fracture.
