Clinico- radiological evaluation of stand alone cage in degenerative cervical spine

Dr. Arvind B Goregaonkar, Dr. Rajesh Srinivas, Dr. Hitesh Shukla, Dr. Jitesh Mangwani, Dr. Amit Singh and Dr. Santosh Bindumadhavan

Abstract
Age-related cervical degeneration is evident in over 50% of the middle-aged population and is the most common cause of neural dysfunction. Cervical spine anteriorly stabilised by use of anterior cervical plate, strut graft, standalone cage or combination to maintain curvature and facilitate arthrodesis. Standalone strut graft has high rate of complications such as graft subsidence, dislodgement, non-union and donor site morbidities. Anterior plating has inherent deficiencies like plate loosening, screw pull out, breakage, trachea-oesophageal irritation has increased operation time. Intervertebral cages avoid some of these difficulties due to their self-fixing construct, ability to contain graft or graft substitute in it. The aim of this study is to compare the clinical and radiological outcome of stand alone cage in single level anterior cervical discectomy and fusion used to treat cervical degenerative disc disease.

We performed a prospective study of 30 patients treated with stand alone -cage in single level cervical disc disease. The clinical and radiological outcomes were evaluated which includes visual analogue scale, Japanese orthopaedic association, neck disability index, neurological status, cobbs angle, fusion and subsidence. Through Smith-Robbinson approach ACDF was done. Patients were assessed up. There is a significant improvement of symptoms reflected by VAS score for pain and functional scores like JOA and NDI. Bony fusion was achieved in 29 patients with a rate of 96.7%. Cervical spine alignment was restored in all patients with kyphosis occurring in 23.3% of patients. Cage subsidence rate was 26.7% with majority occurring in C5-6 level. Anterior cervical discectomy and interbody fusion using stand alone cervical cages can be considered a safe and equally efficient alternative to iliac crest auto graft and anterior cervical plating by providing adequate stability. Stand-alone cage can restore physiologic disc height, provide immediate load bearing support to the anterior column and facilitate arthrodesis.

Keywords: anterior cervical discectomy and fusion, japanese orthopaedic association

Introduction
Spondylosis refers to these age-related degenerative changes within the spinal column. Although the majority of cases are asymptomatic, changes such as disc herniation, osteophyte formation, and hypertrophied ligaments may compress the cervical neuraxis to result in neck pain, radiculopathy, or myelopathy [1]. Several procedures have been described for the treatment of disc herniation and cervical spondylosis when conservative treatment fails, including anterior decompression, laminectomy, laminoplasty and instrumented anterior and posterior fusion by plates or screws. After anterior cervical discectomy, intervertebral fusion can be facilitated by using autograft (iliac crest, fibula), allograft or bone graft substitutes. Standalone strut graft has high rate of complications such as graft subsidence, dislodgement, non-union and donor site morbidities. Anterior plating has inherent deficiencies like plate loosening, screw pullout, breakage, trachea-oesophageal irritation has increased operation time [2,3]. Intervertebral cages have been postulated to avoid some of these difficulties due to their self-fixing construct, ability to contain graft or graft substitute in it. Stand-alone interbody fusion cages represent an alternative for anterior cervical fusion in the treatment of cervical degenerative disc disease. The reason for development of similar fusion device was the...
the avoidance of complications arising from the use of autologous bone graft. Cage-assisted anterior cervical discectomy and fusion (ACDF) has proven to be a safe and effective procedure in available studies. Clinical outcomes have been encouraging in one- and two-level procedures \(^{14-16}\) and reliability was shown even in three- and four-level surgeries \(^{19}\). Cervical intervertebral disc replacement by means of stand-alone cage can restore physiologic disc height, provide immediate load bearing support to the anterior column \(^{21}\) and may facilitate arthrodesis.

**Aims and Objectives of the Study**
To find out short terms clinical and radiological outcomes in patients with degenerated cervical spine.

**Materials and Methods**

1. **Sampling Area**
The study was carried out at Lokamanya Tilak municipal hospital, Sion, Bombay. The study ranged over a period of one year.

2. **Sampling Size**
During the course of this study, thirty patients have been evaluated prospectively. Out of the total 30 patients, 16 were male and 14 were female. Their ages ranged from a minimum of 55 years to a maximum of 73 years. The average follow up is of about one year.

3. **Inclusion Criteria**
All patients who have degenerative changes in cervical spine who underwent single level stand alone cage fixation surgery.

4. **Exclusion criteria**
1. Patients, otherwise meeting the inclusion criteria, were ineligible in case of any of the following criteria
2. Patients sustaining trauma.
3. An earlier operation for cervical disease.
4. Another specific spinal disorder, e.g., ankylosing spondylitis, neoplasm or metabolic diseases.
5. Neurologic disease causing impaired function of the lower limbs, including diabetic neuropathy.
7. Poor General Condition.

5. **Sampling Method**
Most of the patients were those who were being managed on routine out patient department (OPD) for a long term using conservative treatment modalities but without significant benefit. Presenting symptoms included (a) axial pain with neck stiffness radiating upto the subocciput region above or the shoulders below (b) radicular pain with numbness and tingling with or without associated weakness of the shoulder, chest, arms or hands, (c) Motor deficit with atrophy of muscles in upper limbs or lower limbs or both (d)Sensory deficits, (e) Myelopathy causing a wide based jerky gait with weakness and hyporeflexia. Patients with clinical and radiological evidence of cervical spondylosis were included in this study. After institutional ethics committee approval all patients coming to our outpatient department were assessed for inclusion and exclusion criteria.

6. **Parameters to be studied**
1. Pre and post operative neurology.
2. Visual analogue scale.
4. Japanese orthopaedic association(JOA)
5. Cobb's angle(sagittal segmental alignment)

**4 Statistical Methods**
Descriptive and inferential statistical analysis has been carried out in the present study. Results on continuous measurements are presented on Mean ±SD (Min-Max) and results on categorical measurements are presented in Number (%). Significance is assessed at 5 % level of significance. The following assumptions on data is made,

7. **Assumptions**
1. Dependent variables should be normally distributed,
2. Samples drawn from the population should be random.
3. Cases of the samples should be independent
4. Student t test (two tailed, dependent) has been used to find the significance of study parameters on continuous scale between two groups (Inter group analysis) on metric parameters.
5. Student t test (two tailed, dependent) has been used to find the significance of study parameters on continuous scale with in each group. Chi-square/ Fisher Exact test has been used to find the significance of study parameters on categorical scale between two or more groups. Non-parametric setting for Qualitative data analysis. Paired Proportion test has been used to find the significance of proportion in paired data.

Significant figures
Suggestive significance (P value: 0.05<P<0.10)
* Moderately significant (P value: 0.01<P<0.05)
** Strongly significant (P value: P<0.01).

8. **Results and Discussion**
The result of the study is as follows:

1. **AGE**
Of all the patients, the youngest was a female aged 55 years, and the eldest was a male aged 73 years. Maximum patients were in the range of 61-70yrs.

<table>
<thead>
<tr>
<th>Age in years</th>

2. **SEX**
Of the 30 patients, 14 (i.e. 46.7%) were females. The rest 16 (i.e. 53.3%) were males.

![Graph 1: sex distribution](image-url)
3 Duration of Symptoms
Ranged from minimum of 7 months to maximum of 39 months. Maximum number of patients have symptoms duration of 12 to 24 months. Mean duration of symptoms is 18.87±8.51.

Graph 2: Duration of symptoms in months

4 Presenting Symptoms and Neurological Status
Axial neck pain
In current study and as shown in graph-3, thirty patients had axial neck pain pre-operatively. On follow up there was gradual decrease in neck pain. At the follow up at 6 months and 1 year there was 53.3% and 63.3% patients respectively improved in their neck pain.

Graph 3: Axial neck pain distribution from pre operatively through 1 year follow up period.

The patients’ subjective condition was obtained with the Visual Analog Scale (VAS) for pain. A score of 0 mm indicate absence of pain & 100 mm as worst pain even experienced by the patient.

In current study and as shown in table-2, mean pre-operative VAS score was 7.80±0.92. On follow up at 6 months and 1 year, the mean reduction in VAS score is 5.80±1.97 and 5.17±2.12 respectively.

P value -1.067. Chi-Square test.

In our study and as shown in above table, out of 26 patients who had Neuro deficits pre operatively, 19 patients improved in the follow up period. 6 out of 7 patients who has kyphosis shows improvement in neuro deficit during follow up period. Only one patient who has kyphosis doesn’t show Neuro deficit improvement. From the above table, there is no correlation between kyphosis and neurological outcome (p value-1.067).

Ranged from 3 to 5days.

Discussion

Anterior cervical discectomy and fusion is established modality for treatment of degenerative conditions of cervical spine with radiculopathy. 12-14. Goal of fusion after anterior cervical discectomy is to provide stability to spinal column. Use of tricortical graft with plate or biomechanical disc spacers like cage restores the height of the disc space by
relieving buckling of posterior longitudinal ligament and ligamentum flavum. This in turn relieves cord compression and restores volume of the neural foramen thereby decompressing nerve root by the principle of ligamentotaxis. A fusion diminishes neural irritation by limiting motion and by allowing resorption of osteophytes partially [19]. Conventionally, tricortical auto graft is considered gold standard for fusion which provides osteogenic, osteoinduction and osteoconduction properties to graft along with mechanical strength owing to cortical struts in it. Such ideal fulfilments come with another set of concerns like graft collapse, graft extrusion and donor site complications. Graft has poor self-fixing characteristics and it can extrude, collapse or fail to heal resulting in symptomatic pseudoarthrosis [14-16].

Prevention strategy for such complications requires addition or augmentation of fixation with anterior plate system. Minimal invasive harvesting of iliac crest graft aims to minimise various complications of graft harvesting, while giving benefits of autograft. Essentially, it saves surgical time by avoiding complex en-block harvesting of tricortical graft fills cage very well due to cancellous nature. Allograft eliminates donor site morbidity but having chances of disease transfer like HIV or hepatitis, though very rare [17]. Newer surgical techniques attempt to eliminate donor site morbidity and graft related complications. Extrapolating from lumbar spine experience, a titanium cervical cage is proposed as an alternative method for cervical spine fixation and fusion simultaneously providing strength of cortical strut and osteogenic potential with minimal morbidities [17].

Interbody fusion cages rely on the principle of annular tensioning (Ligamentotaxis) restoring disc height and volume and size of neuroforamens indirectly [18]. The main presenting symptom in our series was axial neck pain (100%). At the 1-year follow-up, the improvement of axial neck pain was 63.3%. The other presenting complaint of the patients are Neuro deficits in the form os sensory, motor, and/or bowel and bladder disturbances. 19 patients(63.3%) out of 27 who had Neuro deficits recovered at the end of 1 year follow up. 8 patients continued with the Neuro deficits. It is or more likely that these deficits represent overlap of dermatomes and myotomes from an adjacent or remote level supporting the notion of progression of cervical spine degenerative disease, acting as a major contributor to postoperative sensory and motor deficits [19].

In our series, there was a significant improvement in patient VAS scores at 1 year. Recently, Mehra et al. [20] found that approaching spinal levels above C4 and exposing more than 3 spinal levels were two factors significantly related to voice and swallowing problems. As all our operative levels were below C4 and we did not expose 3 levels in our patients, we did not have any incidence of persistent dysphagia or voice complaints. The JOA score of all patients, were improved after surgery (P < 0.05). The average JOA score pre operatively was 10.53±1.93 and increased to 11.20±2.20 at final follow-up (P < 0.05). The ND1 score also significantly improved from a mean pre-operative score of 27.10±5.22 to 22.77±7.65 at the end of 1 year follow up. There was a significant improvement in patient functional status.

Sagittal segmental alignment (SSA) i.e, coobs angle a good indicator of the efficacy of anterior cervical discectomy and interbody fusion [21]. Comparison between preoperative and postoperative SSA demonstrated the efficacy of our technique for correcting cervical sagittal alignment when degenerative changes produce cervical spine straightening or cervical kyphosis. In our study SSA angles of all patients has improved with a mean pre-operative value of 0.92±1.39 to 4.93±1.30 at the end of one year. SSA angles measured at last follow-up demonstrate a slight loss of correction in comparison with the 6 month postoperative angles, but these changes were not significant, suggesting that the correction obtained with surgery was maintained even after 1 year.

Cervical kyphosis was defined as progression of ≥5° postoperative 12-month follow-up compared to that measured at the immediate postoperative period [22]. Barsa and Suchome [23] have studied stand-alone cage group cervical angulation after 6-month postoperative follow-up. They reported that using Cobb angle resulted about 8.7° loss of segmental lordosis. Also Yang et al. [24] have studied average 1.58° cervical angulation change from immediate postoperative to last follow-up stand-alone cage group. And 29.8% of them changed over 3°. Our studies show that cervical kyphosis was occurred in 23.3%. Cervical kyphosis can occur disc space narrowing and adjacent segment degeneration [25, 26]. In our study kyphosis did not show any adverse outcome in clinical improvement of the patients. The PEEK cage is radiolucent and allowing the surgeon to better evaluate fusion status on radiographs or CT scans. In our series, 29 patients (96.7%) achieved good solid fusion within 12 months (mean months) using a PEEK cage filled with cancellous allograft bone chips. These results confirm those of other studies [27, 28]. In addition to a high fusion rate, successful treatment depends on the maintenance of interspace height and segmental angle [29-31]. Solid arthrodesis was rated according to the following accepted criteria [32-35]. The operated segment was rated as a solid arthrodesis, if movement of less than 2° was measured, and by the absence of motion between the spinous processes on lateral flexion-extension radiographs. Cabrera et al., did not find any statistical difference between two materials of cage with respect to cage subsidence, fusion rates and lordosis maintenance [36]. Thom et al., found cage as safe modality for fusion as compared to tricortical autograft with better functional outcome in cage group with a concern for graft donor site morbidity [37]. An investigator blinded study will larger number of study subjects will establish true clinical superiority of one technique over other.

Conclusion

ACDF with stand alone cages was associated with relatively good clinical and radiologic long-term results. Anterior cervical discectomy and interbody fusion using standalone cervical cages can be considered a safe and effective technique to cure cervical disc herniation with intractable pain or neural deficit in cases where conservative treatment failed. It reliably alleviates cervical degenerative radiculopathy by attaining adequate interbody fusion. It is a safe and equally efficient alternative to iliac crest autograft and anterior cervical plating by providing adequate stability.

Abbreviations

ACDF- Anterior Cervical Discectomy and Fusion.
IÇBG- Iliac Crest Bone Graft.
ND1- Neck Disability Index.
VAS- Visual Analogue Scale.
DID- Degenerative Disc Disease.
SSA- Sagittal Segmental Alignment.
SACS- Sagittal Alignment of Cervical Spine.
